FEBRUARY 1961

BRITISH   BROADCASTING   CORPORATION

FOREWORD

THIS is one of a series of Engineering Monographs published by the British Broadcasting Corporation. About six are produced every year, each dealing with a technical subject within the field of television and sound broadcasting. Each Monograph describes work that has been done by the Engineering Division of the BBC and includes, where appropriate, a survey of earlier work on the same subject. From time to time the series may include selected reprints of articles by BBC authors that have appeared in technical journals. Papers dealing with general engineering developments in broadcasting may also be included occasionally.

This series should be of interest and value to engineers engaged in the fields of broadcasting and of telecommunications generally.

Individual copies cost 5s. post free, while the annual subscription is £1 post free. Orders can be placed with newsagents and booksellers, or BBC PUBLICATIONS, 35 MARYLEBONE HIGH STREET, LONDON, W.1.

TABLES OF HORIZONTAL RADIATION PATTERNS OF DIPOLES MOUNTED ON CYLINDERS

SUMMARY

This monograph contains tables of the horizontal radiation pattern (h.r.p.) of a dipole mounted on a cylindrical mast. The tables were calculated on a digital computer and this enabled a comprehensive range of mast sizes and dipole spacings to be covered.

1. Introduction

Aerials used for VHF broadcasting usually consist of tiers of dipoles mounted on a supporting mast. The number of dipoles in each tier and their relative positions and currents are determined by the required shape of the h.r.p. When an omnidirectional pattern is required, satisfactory results are generally obtained by using a number of dipoles uniformly spaced around the mast and fed symmetrically; in these cases it is convenient to calculate the pattern of the complete array, rather than that of an individual dipole. When a directional pattern is required, the procedure used in the theoretical design is to express the h.r.p. of a single dipole in the form of a complex number, the modulus corresponding to the amplitude of the radiated field and the argument to the phase referred to the axis of the mast. The h.r.p. of the arrangement of dipoles which seems most likely to satisfy the requirements is then calculated by adding the contributions from the individual dipoles. The result obtained will not necessarily be the most satisfactory h.r.p.; changes are therefore made to the dipole positions and currents and the calculation repeated until the best approximation to the required h.r.p. is obtained.

The calculation of the basic h.r.p. (that of a single dipole) is rather tedious, as it involves the summation of a complicated series of terms. A digital computer has, therefore, been used to assemble a library of such h.r.p.s, for dipoles having the three orientations shown in Fig. 1. Formulae for the radiation pattern of a doublet (i.e. a Hertzian dipole) mounted on a cylindrical mast have been derived by Carter,[1] and a brief description of his method, with notes on the application of his formulae to $\lambda/2$ dipoles, is contained in another paper.[2] Although cylindrical masts are not generally used by the BBC, the results obtained may be applied with little error to masts of other cross-sections provided their transverse dimensions are not too large.* Carter's formulae were used for the computations described in this monograph, approximations being made where necessary to obtain the result for dipoles rather than for doublets. The formulae and approximations used are described in the following section.

2. Horizontal Radiation Pattern Formulae

The formulae for the h.r.p. of a dipole and cylinder given in this section are normalized both in amplitude and phase to the maximum field radiated if the cylinder were removed

---

* Carter's formulae may be used for square- and triangular-section masts having faces not exceeding $0\cdot5\lambda$ and $0\cdot3\lambda$ wide respectively. The radius of the equivalent cylinder for a face of width w is $0\cdot59w$ for masts of square section and $0\cdot42w$ for masts of triangular section.
Fig. 1 — Types of dipoles

and the dipole replaced by a similarly oriented dipole, with its centre on the cylinder axis, carrying the same current. The symbols used in the formulae are defined as follows:

$A=$ mast radius in radians

$B=$ distance of dipole from axis of mast in radians

$\phi=$ azimuth angle, measured relative to the angular position of the centre of the dipole or unipole from the mast axis

$J_n(x)=$ Bessel function of the first kind, of order n and argument x

$Y_n(x)=$ Bessel function of the second kind, of order n and argument x

$H_n^{(2)}(x)=J_n(x)-jY_n(x)$ (Hankel function of the second kind, of order n and argument x)

$J_n'(x)$, $H_n^{(2)'}(x)$ denote the derivatives of $J_n(x)$, $H_n^{(2)}(x)$ with respect to x.

2.1 Vertical Dipoles

In the case of vertical elements, Carter's formula for a doublet is also applicable to a dipole. The series converges most rapidly when the contributions from the dipole and from the mast are calculated separately. The expression for the total field, stated in this form, is

$$E=e^{jB\cos\phi}+M_0+2\sum_{n=1}^{\infty}j^n M_n\cos n\phi$$

where

$$M_n=-J_n(A)\frac{H_n^{(2)}(B)}{H_n^{(2)'}(A)}$$

2.2 Tangential Dipoles

Carter's formula for tangential doublets does not apply to tangential dipoles and some error will result if it is used. The error may be reduced by calculating the field radiated by the dipole directly; the doublet source is assumed only when calculating the contribution re-radiated by the mast. The appropriate formula for the total field is then

$$E = \frac{\cos(\frac{\pi}{2}\sin\phi)}{\cos\phi} e^{jB\cos\phi} - j\left[M_o' + 2\sum_{n=1}^{\infty} j^n M_n' \cos n\phi \right]$$

where

$$M_n' = -J_n'(A)\frac{H_n^{(2)'}(B)}{H_n^{(2)'}(A)}$$

This formula is similar to that used for vertical dipoles but the Bessel and Hankel functions are replaced by their derivatives.

2.3 Radial Dipoles and Unipoles

Arrays of radial elements used by the BBC have invariably employed unipoles (or an electrical equivalent) mounted on the surface of the mast. The effective length is generally only $\lambda/4$ and it is therefore permissible to replace them by radial doublets located at the centroid* of the current distribution;[3] this enables Carter's formula to be used with little error. The most rapidly convergent form of the expression is

$$E = \sin\phi\, e^{jB\cos\phi} - j\frac{2}{B}\sum_{n=1}^{\infty} j^n\, n\, Z_n \sin n\phi$$

where

$$Z_n = -J_n'(A)\frac{H_n^{(2)}(B)}{H_n^{(2)'}(A)}$$

3. Range of Values Computed

Radiation patterns were computed for cylinder radii in the range 0·25 (0·25) 2·0 (0·5) 6·0 radians; this covers all the sizes of masts likely to be encountered in the foreseeable future. The smallest size of cylinder (radius 0·25 radians) corresponds to a 1 ft 9 in. (0·53 m) diameter pole at 45 Mc/s. Although smaller supporting poles are sometimes used, their effect is easily calculated because only the first term in the series expansion in the formulae quoted in Section 2 is then significant. The upper limit to the mast radius (6·0 radians or 0·96λ) corresponds to a mast diameter of about 10 ft (3·1 m) in Band III and about 3 ft (0·91 m) in Band V. This limit lies well above the range of sizes for which a cylindrical mast may be assumed as equivalent to a square- or triangular-section mast; the tables for the larger values of mast radius can therefore only be

used for masts of circular, or nearly circular, cross-section.

For vertical and tangential dipoles, patterns were computed for dipoles spaced between 0·5 radians (0·08λ) and 4·0 radians (0·64λ) from the surface of the cylinder. For radial unipoles, patterns were computed for a doublet spacing of 0·5 radians only; this spacing corresponds very closely to the position of the current centroid of a $\lambda/4$ unipole. Calculations were made with these spacings for the chosen range of cylinder radii, making a total of 272 tables.

The real and imaginary components of the patterns are tabulated at 15° intervals in the range $0 \leqslant \phi \leqslant 180°$, the columns being headed R and I respectively. Tabulation for the remaining 180° was not necessary as the h.r.p.s are either symmetrical or skew-symmetrical (depending on the dipole orientation) with respect to the centre line. Each table is headed by V, T, or R (vertical, tangential, or radial) followed by the values of A and B.

The computer programme was arranged to work through the whole range of variables without a break, the changes in the parameters A and B being made automatically. As these two parameters between them cover only a small number of radial distances, it was found to be more convenient to feed tabulated Bessel functions into the computer rather than use a time-consuming sub-routine to calculate them. Bessel functions of the first and second kind, of zero and first order only, were stored in the computer; the higher order values were obtained from the recurrence formula, and their derivatives from the difference formula. Numerical values of $\cos\phi$ and $\sin\phi$ were also stored; only seven actual numbers were required, a special sub-routine being used to choose the appropriate value of $\cos\phi$ or $\sin\phi$ and give it the correct sign.

4. Conclusions

The tables of h.r.p.s should satisfy most requirements arising in the design of v.h.f. aerial systems for broadcast transmitters. Although applicable to cylindrical masts, they may be used with little error for masts of square or triangular cross-section provided the widths of the mast faces do not exceed 0·5λ and 0·3λ respectively. The tables are intended not merely to give the pattern of a single dipole but also to simplify the calculation of the patterns of arrangements of more than one dipole spaced around a mast; this is achieved by appropriate addition of the contributions of each dipole and an analogue computer[4] has been developed in the BBC Research Department to facilitate this operation.

* We have to imagine that the unipole has a mass distributed along its length, the mass per unit length at any point being proportional to the current at that point. Then the centre of gravity (or centroid) of this mass would correspond to the centroid of the current distribution.

NOTES ON THE USE OF THE TABLES

There are three sets of tables, for vertical and tangential dipoles and for radial unipoles. Each table is headed by the cylinder radius in radians (A) and the distance of the dipole or unipole from the cylinder axis, also in radians (B). The left-hand column of each table gives the angle ϕ between the direction of the observer and the position of the radiating element. The other columns, headed R and I, give the real and imaginary components of the horizontal radiation pattern, referred in phase to the cylinder axis. Values are not given for ϕ greater than 180° because the patterns are symmetrical about $\phi=0$ for vertical and tangential dipoles and skew-symmetrical (values equal in magnitude but opposite in sign) about $\phi=0$ for radial unipoles.

In order to minimize the possibility of errors, the lists of figures actually printed by the digital computer have been reproduced in these tables. This accounts for the variations in the standard of reproduction of the figures in some of the tables.

A RECENT BBC DEVELOPMENT

**G. A. HUNT, DESIGNS DEPARTMENT,
ENGINEERING DIVISION**

Modifications have been made to the 'synchro-guide' circuit to overcome certain defects in its performance. Details of the unmodified circuit are shown in Fig. 1. The purpose of the circuit is to provide a regular line time base from an irregular or disturbed television signal.

Referring to Fig. 1, the signal on the grid of valve V_1 consists of positive-going syncs and a sawtooth waveform derived from the blocking oscillator valve V_2. Valve V_1 conducts only during the periods when the syncs overlap the latter portion of the sawtooth waveform since it is biased to 'cut-off' by the anode current through resistor R_1 smoothed by capacitors C_1 and C_2 and the RC network R_4C_3. The current flowing through valve V_1 for this period generates a potential difference across resistor R_3 which controls the repetition frequency of the blocking oscillator valve V_2. The circuit then adjusts itself so that the phase relationship between syncs and the sawtooth waveform is such that the correct current flows through valve V_1 and hence resistor R_3, thereby biasing valve V_2 to give the correct mean repetition frequency. The circuit suffers from a degenerative effect since increasing current through valve V_1 increases its bias, nullifying to some extent the increased conduction period.

To overcome the above defect the improved arrangement shown in Fig. 2 has been devised. In this arrangement the bias for valve V_1 is obtained from the grid current to valve V_2 flowing through resistor R_3, smoothed by the capacitor C_2. Since the mean grid current is nearly constant, an almost constant bias may be obtained for valve V_1 and the current through valve V_1 does not affect this bias and therefore the degenerative effect present in the original circuit is removed.

A simplification of the circuit shown in Fig. 2 may be achieved by removing capacitor C_3 and resistor R_4, under which conditions the circuit for feeding back a sawtooth waveform from the output to the grid of V_1 may no longer be necessary.

The advantages claimed for the modified arrangements are:

1. No degenerative effect takes place in valve V_1 and thus a greater control voltage may be obtained for a given change of phase.

2. A greater locking range may be obtained.
3. The circuit requires fewer components.

Fig. 1 — *Unmodified synchro-guide circuit*
